

SpatialPlanet AI

The AI Operating System
for a
World Wide Web of Intelligence

Creates the largest potential AI application marketplace

(The Company is still in Stealth Mode)

1. The new Spatial Web of AI has at its core a new type of Decentralized AI and a new set of Spatial Web Protocols.

We are entering a new era for the global Internet called
The Spatial Web of Intelligence.

Until now, the Internet has been limited to email and the Webpages. We now have the protocols for an AI Web and this document guides you through the amazing opportunities it creates.

A short history of the Internet:

In 1970, the Internet began with Email.

This created a Global Web of Communication

The Protocol is TCP/IP – enabled email

*By 1994, there were 15 million computers
and 40 million people connected.*

**In 1994, the Internet added 2D Webpages and Websites
This created the World Wide Web of Information**

The Protocols are HTTP/HTML – enabled web
*By 2026, there were 40 BILLION computing devices
and 6 BILLION people connected.*

**In 2026, the Internet added 3D Webspaces and Spatial AI
This will create a Global Spatial Web of AI Intelligence**

The Protocols are HSTP/HSML – enables global intelligence
*By 2040, there will be over a Trillion AI agents, over 10 Billion
Robots and over 7 Billion people connected to the Spatial Web,
creating a network mainly for AI - by AI.*

**The Global Internet began in 1970 and in the past 55 years
humanity has spent over \$200 Trillion building it out – and
it's growing fast than ever. However, its biggest growth is
still to come as we move from 2D webpages to 3D models
and a new world of AI Agents, Robots and Web Spaces.**

(SIZE of the Internet) Over 3 Billion miles of Fiber Optic
cables accounting for nearly \$200 Trillion alone, over 40 Billion
digital devices connected to the global Internet, 10 Billion are
smart phones – the Internet is MASSIVE.

A Spatial Web of Intelligence / The Next Internet

Two New Technologies enable this AI Internet

i. The first technology is a new Internet Protocol set called the Spatial
Web Protocols. The Spatial Web Foundation and the IEEE standards
body have just completed work on the HyperSpace Modeling Language
– HSML – and the HyperSpace Transaction Protocol – HSTP - which
enables a Web of Smart Spaces or Spatial Intelligence.

ii. The second is a new type of decentralized AI, called Active Inference AI, that is much smaller than LLMs because focused on a single topic. Creating this type of AI is similar to creating a website or an App. A person or an organization can download the tools and create an AI application locally – anywhere in the world.

Because the AI is already compatible with the Spatial Web, all AI Apps are available online to everyone just like websites are now. This enables the decentralized development of Smart cities, smart farms, smart ports, etc. This new AI Web will rapidly unlock and share the knowledge of humanity globally and while also creating an ongoing co-evolving partnership between humans and AI.

2. What about LLM AI?

LLMs are yesterday's AI – Active Inference is tomorrow's AI

All LLM AI systems hallucinate and they will always hallucinate. They are designed to predict a “probable” answer from stored data. But many real-world applications need real-time accuracy – banking, law, medicine, logistics, manufacturing, smart cities and many more.

Active Inference AI has been designed to correct for this LLM design flaw. Active Inference does NOT hallucinate – it functions like a human being and interacts with the world in real-time via sensor data. Accurate results are based on real-time measurements rather than looking to stored training data for a “probable” answer.

Active Inference solves every problem that LLMs currently face and can do many things that LLMs are actually incapable of doing.

LLMs for Content vs. Active Inference for Operations

LLMs are fine for creating Content: reports, code, images. But they randomly hallucinate (errors) and therefore need a human editor to correct any errors before use. Also, they are a black box and there is no way to audit them – which makes

them useless for banking applications, business, medicine, law and other real-time operational systems. Despite these fundamental problems, LLMs are valuable labor-saving tools if we limit their applications to creating Content. One of the other major problems is that they are not profitable to operate. Their creation and operating costs are too expensive to ever become profitable. But even more dangerous, it is possible to create Open-Source (free) versions of LLMs and Deep Seek in China is just one example of many. LLM AI is not a viable standalone business but it will become a service layer in the next Internet.

Active Inference AI was designed precisely for accurate Operations. It can do this because it does not hallucinate. It measures the world in real-time. Therefore, it can be used for real-time AI Operations such as managing global banking, operating a hospital, controlling millions of robots or automobiles, managing an entire smart city and monitoring the many variables in our global climate. These activities all involve moving large amounts of money or data across networks in real-time with no opportunity to have a human involved. These systems must be accurate and be able to be audited for legal reasons. Active Inference AI therefore has no limits on its potential applications. Lastly, it's incredibly inexpensive to create and operate Active Inference AI making it profitable immediately.

SpatialPlanet AI has created a new **Active Inference AI Platform** to support the development of Active Inference AI Agents and Apps and, along with it, an **AI App Store** where you can find every new Agentic Application as they are developed and released. These Active Inference AI applications and Agents can all exchange information with each other on the global Internet. This enables true **Decentralized AI**.

The interface to the SpatialPlanet App Store is an **AI Customer Support Agent** that will assist individuals and organizations to identify the right AI App for their particular application.

3. The Problem / Solution for AI Systems

Problem: The modern world is overwhelmed by complexity. Markets, supply chains, cities and healthcare systems produce more data than we can coherently act on. Current LLM AI excels at generating even more content but it only provides the best “probable” answer – not the accurate answer. This approach creates many random errors (called hallucinations) and is therefore NOT SAFE or reliable for real-time operations. And real-time operations are projected to be 90 pct of what

AI is used for in the coming years.

Solution: Two technologies combine to create Active Inference Solutions

- a. Active Inference AI:** Based on the free-energy principle, active-inference agents continuously update a generative model of their environment. They make predictions, take actions to test those predictions, and adjust their model using incoming sensor data. In other words, the LEARN and ADAPT. True Intelligence is defined by maintaining an accurate, evolving world-model rather than memorizing massive datasets.
- b. Spatial Web:** The new IEEE Spatial Web standard extends the internet to include digital twins of physical systems. These digital twins can now be updated with real-time data and connected through shared protocols, enabling data integration and action across domains.
- c. Additional Technologies:** Other critical technologies can dock into this tech stack such as CyberSecurity software, IoT links, Blockchain technologies, Metaverse Interfaces and other yet to be invented technologies that will appear in the coming years.

Operational Internet: When active-inference agents live inside digital twins on the Spatial Web, they form a network of “domain-specific” models that learn and act together. Decisions can be made locally but informed by a global view of the system. This distributed intelligence layer is called the Operational Internet.

Benefits:

Real-time adaptation: Agents can sense, predict and act continuously, adapting to disruptions and uncertainties (e.g., rerouting supply chains, adjusting hospital operations).

Less data, more efficiency: Domain-specific models require far less training data and can run on edge devices—making them energy-efficient and explainable.

Interoperability and governance: The Spatial Web creates a shared, auditable environment in which agents can collaborate securely while respecting local autonomy.

Cross-domain coordination: Digital twins integrate data from multiple systems (traffic, energy, healthcare, finance, manufacturing), enabling coordinated responses and optimization.

Scalability: The same architecture applies to individual robots, city infrastructure and global supply networks.

It's an operating system for civilization.

Takeaway: By combining Active Inference with the Spatial Web, we move from an internet that *informs* us to an internet that takes *action*—creating a World-Wide Web of Intelligence that can manage complexity and drive real-world operations.

4. Spatial Planet Business Summary

SpatialPlanet has created an AI Tech Stack for a new type of AI App that does not hallucinate. All existing web and mobile Apps will convert to AI Apps in the next 36 months. We can automate most of it.

1. The Spatial Web is the next and largest software platform

It is the Fourth Major Software platform.

1. IBM PC and Clones running MS-Dos: launched the independent software industry
2. The World Wide Web: launched the multi-trillion dollar Website economy
3. The Smart Phone and the App Store: launched the 10 million App market
4. The Spatial Web and AI Agents: will launch the trillion Agent market.

Microsoft MS-DOS

When IBM launched the Personal Computer in 1981, it ran on MS-DOS - a Microsoft Operation System. As IBM PC compatible computers proliferated, MS-DOS became the standard Operating System for millions of Personal Computers. The independent software industry then exploded in the 1980s and 90s, precisely because **MS-DOS became the dominant standard** across PC clone companies.

When IBM chose Microsoft's operating system for the IBM PC in 1981, it established a baseline. As clone manufacturers (like Compaq, Gateway, and Dell) reverse-engineered the IBM architecture to run MS-DOS, they created a massive, unified install base. Developers could write a program *once* and sell it to millions of users across dozens of hardware brands.

Developing high-quality commercial software is expensive and time-consuming. Because MS-DOS became the predictable, dominant standard, software publishers faced significantly less financial risk. They knew that if they built a great product, the target market was massive and growing exponentially. This certainty attracted venture capital and entrepreneurial talent into the software sector.

The World Wide Web Standard

The World Wide Web followed in the mid-90s and grew rapidly because it transformed the internet from an email system into a content delivery system. Websites were an intuitive, visually appealing, and universally accessible system. By combining **hypertext**, simple **browsers**, and **open standards**, it removed technical barriers, allowing anyone to easily discover and share information or create a website of their own.

Apple App Store

The next platform was from Apple. Apple created the concept of Apps and then invited the world to create Apps which they would make available in the Apple App Store. Apple only creates approximately 70 Apps and people and enterprises all over the world have added another 5 to 10 million Apps.

Companies like Uber and AirBnB and thousands of others became successful because of the App Store. Apple still builds a small number of Apps (less than 70) but 99.99% of all Apps are created by 3rd parties who pay Apple a percentage of the revenues of each App. **In 2025, Apple grossed US\$117 Billion and retained US\$27 Billion for a net percentage of 23% of total revenues in the App Store.**

Fast forward 18 years to today and we are now entering the **Age of Operational AI**. Operational AI requires the creation of advanced Agents and Applications that can help with education, medicine, finance and big things like managing Supply Chains, Cities, Hospitals and Airports. LLMs are not designed to do this.

The Largest Platform of All is Now Launching – The Spatial Web.

SpatialPlanet AI Platform launches later this year. It includes embedded services such as AI, blockchains, spatial computing, network protocols and IoT sensor access that enables the development of advanced AI applications called Agents and AI Apps.

SpatialPlanet is a tech stack with components that make it easy for individuals and companies to create their own Advanced AI Apps and Agents. These Apps can then be found in the SpatialPlanet App Store. AI developers globally can download the SpatialPlanet tech stack and any business or individual can use this tech stack to create AI Apps for any purpose.

5. The SpatialPlanet Opportunity

The SpatialPlanet AI Platform represents a generational investment opportunity because SpatialPlanet has not merely developed another artificial intelligence application. It is creating a new global platform to enable developers worldwide to create advanced AI Apps and Agents and to use the SpatialPlanet App Store to market them.

The SpatialPlanet tech stack will define the next era of the Internet. We are now evolving from today's World Wide Web of Information - an Internet of webpages - to an "Operational Internet" that networks these Operational AI applications together worldwide to enable our world to function more effectively and efficiently.

The next generation of Operational AI systems will go beyond today's LLMs and will not simply store, transmit, and retrieve information, but **sense, model, decide, and act** in real-time across physical and digital environments. The world is moving from an internet of content and

information to an internet of actions and operations, and SpatialPlanet has architected the intelligence platform required to make that evolution possible.

Individuals and organizations worldwide will be able to use our new tools to create applications like Smart Cities, Smart Farms, Smart Supply Chains and exciting new entertainment, education, finance and medical applications. And just like Apple's App Store, SpatialPlanet will be paid a percentage of each AI application running on this global network.

The opportunity is huge - mainly because of the fundamental limitations in today's dominant LLM AI paradigm. Large Language Models – LLMs - have demonstrated extraordinary usefulness in content creation, summarization, conversation, coding assistance, and pattern recognition. However, these systems have built-in design problems that lead to random errors. LLM technology is fundamentally probabilistic – in other words they are making probable guesses as answers – and that means that they are not perfectly accurate and error-prone. Added to that, they cannot be AUDITED – which is critical for autonomous systems. This limits their use to Content that can be reviewed and corrected by human editors.

This leaves the massive market for Real-Time Operational AI completely UNTOUCHED. And this market is much larger than the market for LLM AI content – and much larger than today's World Wide Web of commerce and information.

SpatialPlanet's Active Inference AI is a breakthrough that provides the accurate intelligence layer. Rather than passively analyzing data and producing predictions, Active Inference agents continuously observe their environment, update their internal models, form hypotheses, and take actions that reduce uncertainty. This is a huge breakthrough and creates an intelligence system in which perception, reasoning, planning, and action are integrated. The practical significance is profound. These systems are built to understand causal relationships, anticipate downstream consequences, adapt to new environments, and operate in changing environments where historical data alone is insufficient. Nothing else comes close.

When Active Inference agents are embedded inside Spatial Web environments, each AI agent can model a domain, coordinate with other agents, and optimize outcomes across interconnected systems – critical for applications like Smart Cities and Supply Chains. This World Wide network of Operational AI applications creates a distributed intelligence architecture that mirrors the complexity of the real world.

The end result of this combination of technologies is the “Operational Internet”. In this model, the internet becomes a Real-World Management System. The Operational Internet understands the current state of the world, models possible futures, makes real-time decisions, and executes actions across systems. This is a fundamental shift from data to decisions and from information to actions. The SpatialPlanet Operational AI is not pursuing a narrow software category. It is creating a new platform layer upon which many other operational applications can be built.

The Operational Internet will function as an “operating system for the next civilization”. Modern civilization is composed of deeply interconnected but poorly coordinated systems: financial networks, supply chains, energy grids, transportation systems, healthcare institutions, governance

processes, and urban infrastructure. Each of these systems operates with different data structures, rules, incentives, and constraints.

Today, these systems are fragmented, siloed from one another and often unable to respond intelligently to rapidly changing conditions. SpatialPlanet's integrated architecture creates a unifying layer that allows these systems to share a common representation of reality, coordinate decisions in real time, and adapt collectively. In the same way that computer operating systems manage interactions between hardware and software, SpatialPlanet's platform manages interactions between intelligent agents, digital twins, institutions, and real-world assets.

CONCLUSIONS

The economic implications are substantial. The largest technology companies in history captured massive value because they controlled the foundational layers. Microsoft captured the desktop operating system. Amazon captured cloud infrastructure. Google organized the world's information. SpatialPlanet's technology stack creates a World Wide Web of Intelligence and using that to turn intelligence into actions. SpatialPlanet's value will not come from one product or one vertical market. It will come from licensing its technologies to create a coordination layer across multiple trillion-dollar sectors, including AI infrastructure, enterprise software, logistics, finance, smart cities, defense, infrastructure management, and national security.

The investment opportunity is especially compelling because the platform architecture will be similar to a combination of Apple's App Store and the billion websites on the World Wide Web. There will be strong network effects, recurring revenues and there will be no real alternative for some time.

In the coming year, SpatialPlanet can enter the market through specific industry applications where operational intelligence creates measurable value, such as reducing supply-chain disruption, improving asset utilization, optimizing infrastructure, or supporting complex enterprise decision-making. As more organizations deploy agents and digital twins, the network becomes more valuable. Just as it was with the World Wide Web, each additional participant increases the richness and value of the shared operational environment. Over time, the SpatialPlanet Operational AI Platform can evolve from an initial platform provider into a critical network infrastructure layer that enterprises and governments depend on to coordinate real-time activity both locally and globally.

The current competitive landscape also makes SpatialPlanet a great investment. All of the large LLM AI companies like OpenAI, Anthropic, Grok, Google and others are completely focused on building massive datacenters and Hyperscaling the current LLM models. They really don't compete in the real-world automation applications that SpatialPlanet's platform is designed for.

Likewise, existing Enterprise software companies like Oracle and Salesforce are largely optimizing legacy architectures by adding LLM tech to their software. Blockchains are generally siloed use cases and lack the standardized intelligence, causal modeling, and operational interoperability required for real-time coordination.

SpatialPlanet's differentiation is that it is not simply improving existing software categories. It is proposing a more capable overall architecture for intelligence itself, one designed for managing operational environments rather than what LLMs do which is simply generating Content in the form words, images or code. SpatialPlanet is the Operational Layer that ultimately functions as an Operating System for the planet.

True Operational Intelligence is finally here and the era of LLMs is passing.
